

FEVER MANAGEMENT GUIDELINES

This document contains sample medical information for testing a RAG-based medical question answering system.

Definition of Fever

Fever is a temporary increase in body temperature, usually caused by infection or inflammation. A temperature above 38°C (100.4°F) is generally considered fever.

Common Causes of Fever

- Viral infections such as influenza and COVID-19
- Bacterial infections such as pneumonia and urinary tract infections
- Inflammatory diseases
- Heat exhaustion
- Certain medications

Symptoms Associated with Fever

- Elevated body temperature
- Chills
- Sweating
- Headache
- Muscle pain
- Fatigue
- Loss of appetite
- Dehydration

Diagnosis

Doctors may diagnose fever using clinical examination, thermometer readings, blood tests, urine tests, and chest X-rays if infection is suspected.

Treatment of Fever

For mild fever, rest and hydration are recommended.

Common medications:

- Paracetamol (Acetaminophen)
- Ibuprofen

When to Seek Medical Attention

Immediate medical care is recommended if:

- Fever exceeds 40°C
- Difficulty breathing occurs
- Severe chest pain develops
- Persistent vomiting occurs

- Fever lasts more than 3 days
- Patient becomes unconscious

Fever in Children

Children with fever should be monitored carefully. Medical attention is required if the child is younger than 3 months, experiences seizures, becomes unusually sleepy, or has persistent crying.

Prevention

- Regular hand washing
- Vaccination
- Safe food handling
- Wearing masks during outbreaks

Important Notes

Antibiotics should only be used for bacterial infections and must be prescribed by a licensed doctor. Self-medication should be avoided.
